Performance Testing and Surrogate Tests for Quality Control

Thomas Bennert, Ph.D. Rutgers University Center for Advanced Infrastructure and Transportation (CAIT)

NJDOT Performance Related Specifications (PRS)

- NJDOT developed PRS using the Asphalt Pavement Analyzer (AASHTO T340) and Overlay Tester (NJDOT B-10)
- Criteria established for different mixes based on research and field performance history

Is there a need for surrogate test methods?

- Implementing Performance Related Specifications (PRS) and Balanced Mixture Design (BMD)
 - Mixture Design
 - Quality Control
 - Quality Acceptance
- Asphalt suppliers' comments regarding PRS testing;
 - "Too expensive to purchase equipment"
 - "Takes too long to get back test results"
 - "Test methods not suited for Quality Control work"
- To effectively implement BMD and PRS, may need to utilize surrogate test methods during Quality Control

Is there a need for surrogate test methods?

- Goal of Study:
 - Determine if a rutting and fatigue cracking suite of test methods can be used as "surrogate tests" during QC work at asphalt plants for NJDOT.
 - "Surrogate tests" proposed for QC guidance, not acceptance
 - Must have strong correlation to PRS test methods
 - Presented test methods may also provide other agencies with a starting point if existing test methods not being used

Who Remembers This?

- Most plants still have Marshall equipment
 - TSR's
 - FAA work
- Proposing the use of Marshall equipment as the loading frame for new tests
- Rutting and cracking performance can be assessed with minor investments using IDT set-up

History of IDT

- Developed in Brazil (Carneiro, 1943) and Japan (Akazawa, 1943) at same time to determine tensile strength of concrete
- Livneh and Shklarsky (1962) first to use it for HMA (cohesive properties)
- Kennedy and associates at U. of Texas looked at both static and dynamic properties in IDT in 70's & 80's (resilient modulus)
- SHRP program recommended for low temperature cracking
- Penn State (2001, 2004) and AAT (2004, 2007) recommended for rutting properties (NCHRP 9-33)
- TTI (2016) and NCAT (2017) developed similar procedures for fatigue cracking

Rutting (Permanent Deformation)

IDT Related to Permanent Deformation

- Indirect tensile strength (IDT) is related to the shear strength of materials
 - Mohr-Coulomb
- Rutting a function of the shear strength
 - Cohesion (C) ≈ binder properties
 - Friction (\$\$) ≈
 aggregate properties

Rutting – High Temperature IDT (HT-IDT)

- High temperature IDT (NCHRP 9-33 Recommendations)
 - Uses TSR IDT frame with Lottman head (used for TSR; AASHTO T283)
 - Gyratory compacted samples (set air void level to specified)
 - 50 mm/min (2 inch/min) deformation rate
 - Test temperature is 10°C lower than local climate (LTPPBind 3.1, 98% Reliability, 20 mm below surface, not corrected for traffic or vehicle speed)

HT-IDT Laboratory Evaluation

- Compared variety of lab and plant produced HMA using APA and HT-IDT
- RAP, WMA, NMAS, binder grades
 Used NJDOT PRS criteria for rutting (APA) for criteria development

NJDOT PRS Asphalt Mixture	Asphalt Pavement Analyzer Rutting Requirement	
High Performance Thin Overlay (HPTO)	< 4 mm	
Bituminous Rich Intermediate Course (BRIC)	< 6 mm	
High RAP - Surface Course	< 4 mm	
High RAP - Inter/Base Course	< 7 mm	

HT-IDT vs APA Rutting – Preliminary Guidance Values

- Error bars represents average COV
 - APA = 9.6%; HT-IDT = 6.0%

- Open Symbols from NCHRP 9-33
- Filled Symbols Rutgers data
- Black line correlation
- Red dotted line is proposed Pass/Fail criteria that includes HT-IDT COV%

HT-IDT vs APA Rutting – Preliminary Guidance Values

NJDOT PRS Asphalt Mixture	Asphalt Pavement Analyzer Rutting Requirement	HT-IDT Strength Requirement
High Performance Thin Overlay (HPTO)	< 4 mm	> 47 psi
Bituminous Rich Intermediate Course (BRIC)	< 6 mm	> 30 psi
High RAP - Surface Course	< 4 mm	> 47 psi
High RAP - Inter/Base Course	< 7 mm	> 25 psi

Fatigue Cracking

Fatigue Cracking of Asphalt Mixtures

- Rutgers has been evaluating a number of fatigue cracking test methods for use within PRS, BMD, and Quality Control
 - Compared test methods to field performance
 - Results showed Overlay Tester and SCB Flexibility Index had best comparison
 - Similar findings at TTI, U. of Illinois
 - Overlay Tester requires own equipment and time consuming

Fatigue Cracking Laboratory Evaluation

- Compared variety of lab produced mixes
 - NMAS, binder grades, aged conditions, asphalt contents
- Used NJDOT PRS criteria for fatigue cracking (Overlay Tester) for criteria development
 Compared 2 potential
 - test methods for potential Overlay Tester surrogate

NJDOT PRS Asphalt Mixture	Overlay Tester Fatigue Cracking Requirement	
High Performance Thin Overlay (HPTO)	> 700 cycles	
Bituminous Rich Intermediate Course (BRIC)	> 700 cycles	
High RAP - Surface Course	> 175 cycles	
High RAP - Inter/Base Course	> 100 cycles	

SCB Flexibility Index (AASHTO TP124)

Standard Method of Test for Determining the Fracture Potential of Asphalt Mixtures Using Semicircular Bend Geometry (SCB) at Intermediate Temperature

AASHTO Designation: TP 124-16¹

AASHC Technical Section: 2d, Proportioning of Asphalt

Release: Group 3 (August 2016)

1. SCOPE

-Aggregate Mixtures

- This test method covers the determination of the fracture energy (G) of asphalt mixtures using 1.1. the semicircular bend (SCB) geometry at an intermediate test temperature. The method also includes procedures for calculating other relevant parameters derived from the loaddisplacement curve. These parameters, in conjunction with field performance, can be used to develop a Flexibility Index (FI) to predict an asphalt mixtures' damage resistance. The index can be used as part of the asphalt mixture approval process.
- 1.2. These procedures apply to test specimens having a nominal maximum aggregate size (NMAS) of 19 mm or less. Lab compacted and field core specimens can be used. Lab compacted specimens shall be 150 ± 1 mm in diameter and 50 ± 1 mm thick. When field cores are used, specimens shall be 150 ± 8 mm in diameter and 25 to 50 mm thick. A thickness correction factor may be applied for field cores tested at thickness less than 45 mm.
- A vertical notch parallel to the loading axis shall be cut on the SCB specimen. The SCB 1.3. specimen is a half disc with a notch parallel to the loading and the vertical axis of the semicircular disc.
- This standard does not purport to address all of the safety concerns, if any, associated with its 1.4. use. It is the responsibility of the user of this standard to establish and follow appropriate health and safety practices and determine the applicability of regulatory limitations prior to use.

Overlay Tester vs SCB FI – Preliminary Guidance Values

Error bars represents average COV

- Black line correlation
- Red dotted line is proposed Pass/Fail criteria that includes SCB-FI COV%

Overlay Tester vs SCB FI

- Advantages of SCB FI over Overlay Tester for Quality Control testing
 - Quicker testing time
 - Inexpensive equipment
 - Quicker specimen prep time (no gluing)
 - Less specimens (OT needs 5 gyratories; SCB FI needs 2 gyratories)
- Some drawbacks of SCB FI for Quality Control
 - Requires wet saw in lab
 - Requires sawing and notching for sample prep
 - Some data analysis required Spreadsheets available

Fatigue Cracking – IDEAL-CT (Zhou et al., AAPT 2017)

- Fatigue Cracking (IDEAL-CT Recommendations)
 - Uses TSR IDT frame with Lottman head (used for TSR; AASHTO T283)
 - Gyratory compacted samples (set air void level to specified)
 - 50 mm/min (2 inch/min) deformation rate
 - Test temperature is 25°C

IDEAL-CT vs Overlay Tester Fatigue Cracking – Preliminary Guidance Values

- Error bars represents average COV
 - OT = 24.5 %; IDEAL-CT = 16.5%

- Black line correlation
- Red dotted line is proposed Pass/Fail criteria that includes IDEAL-CT COV%

Overlay Tester vs IDEAL-CT

- Advantages of IDEAL-CT over Overlay Tester for Quality Control testing
 - Quicker testing time
 - Inexpensive equipment
 - Quicker specimen prep time (no gluing)
 - Less specimens (OT needs 5 gyratories; IDEAL-CT needs 3 gyratories)
- Advantages of IDEAL-CT over SCB-FI for Quality Control testing
 - No sawing or notching required
 - Data analysis required Spreadsheets available

Resultant Fatigue Cracking Criteria

NJDOT PRS Asphalt Mixture	Overlay Tester Fatigue Cracking Requirement	SCB Flexibility Index	IDEAL-CT Fatigue Cracking Requirement
High Performance Thin Overlay (HPTO)	> 700 cycles	> 18	> 245
Bituminous Rich Intermediate Course (BRIC)	> 700 cycles	> 18	> 245
High RAP - Surface Course	> 175 cycles	> 11	> 150
High RAP - Inter/Base Course	> 100 cycles	> 9	> 120

Surrogate Testing for Quality Control of BMD & PRS

- Quality control testing important part of mixture production
 - Within BMD and PRS, performance testing should be required
- Issues with performance testing during QC
 - Time for testing and analysis
 - Cost (equipment, supplies) and space requirements
 - Trained technicians
- Surrogate testing may aid in these issues
- The suite of IDT test methods presented show potential for use during Quality Control, as well as Mixture Design and Acceptance during BMD and PRS programs
- TRB 2018 Paper (#18-05836) for more details
